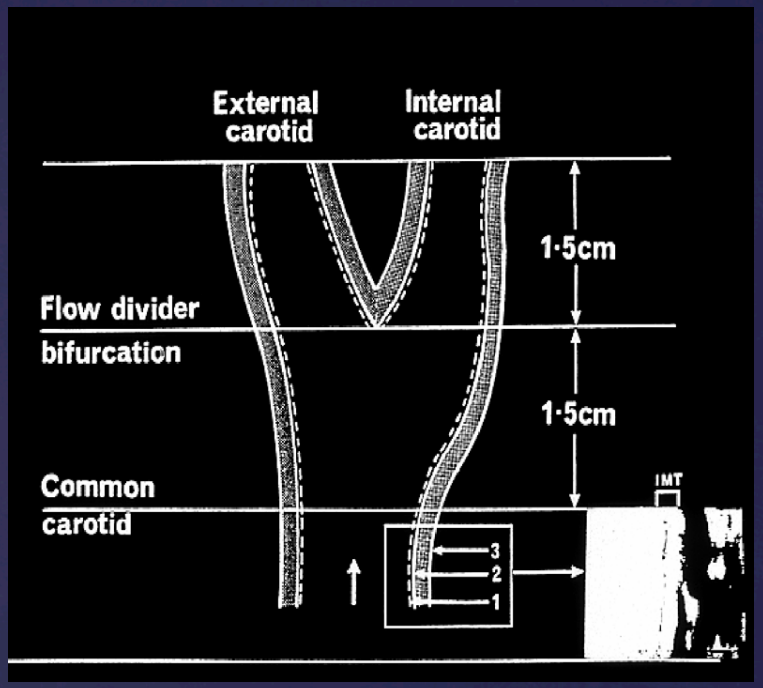
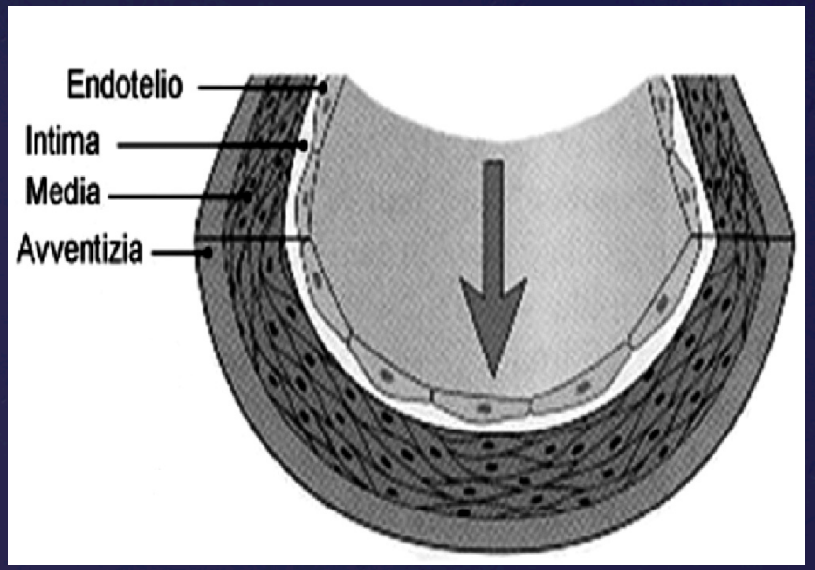
Imaging carotideo: dall'IMT alla pulse wave velocity

(Asymptomatic organ damage)

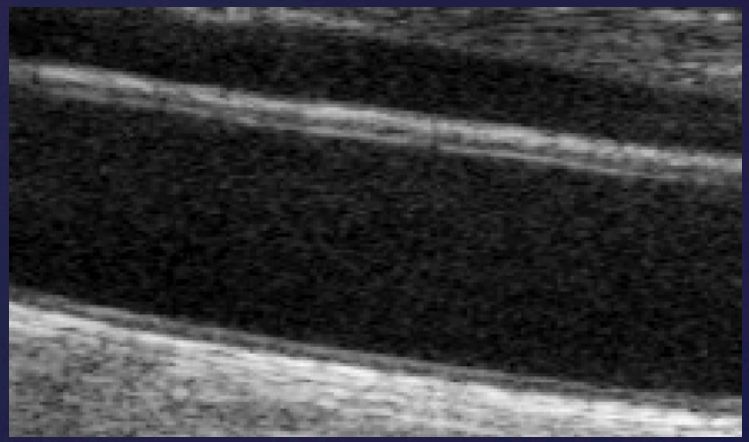
Olga Vriz

San Daniele del Friuli





carotid artery demonstrated a 'double-line' pattern: the first echogenic interface on the far wall corresponds to the lumen–intima interface and the second arises from the media–adventitia interface.



San Daniele del Friuli

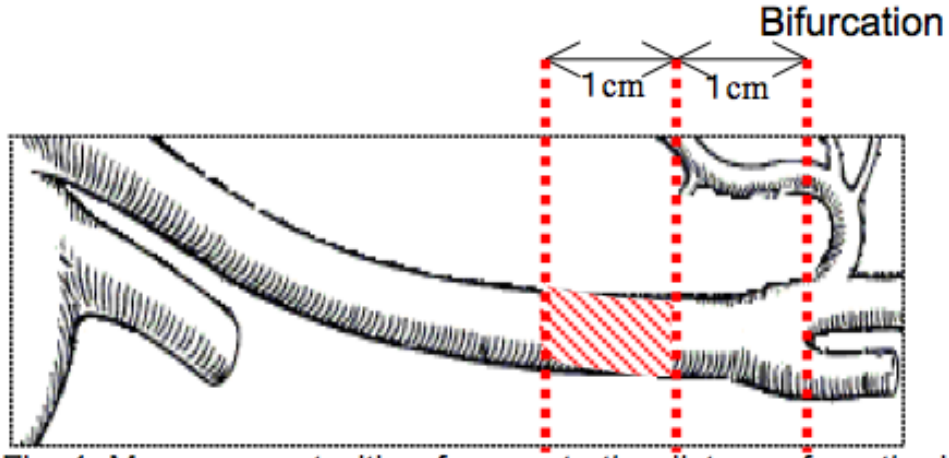


Fig. 1: Measurement with reference to the distance from the branch

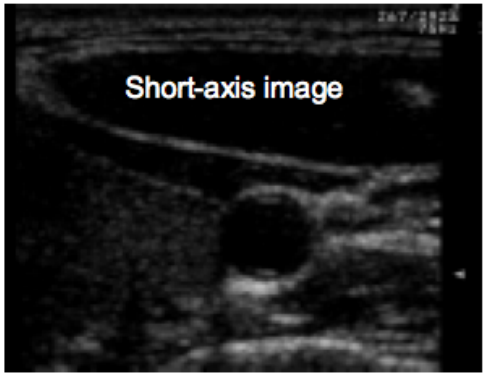
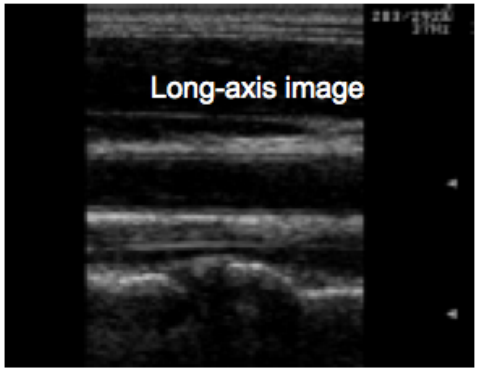
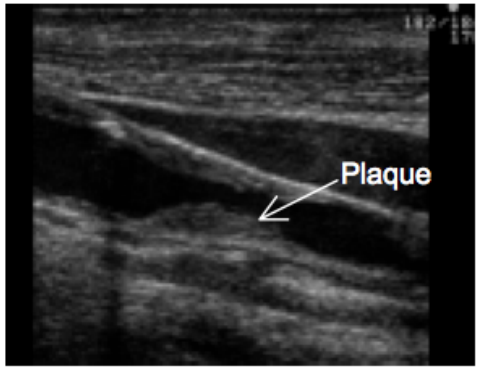


Short-axis images have the advantage that the maximum diameter of a blood vessel can be easier to recognize.



Long-axis images have a smaller variation when the effect of vein pulsation is strong.



Avoid the part where plaques and others are formed.

Table 5 Recommend scanning protocol for evaluation of common carotid artery carotid intima-media thickness and detection of carotid plaques

Step	View	Area of interest	Technique	Use
1	Transverse B-mode scan (3-5 beat cine-loop in each segment)	From proximal CCA through middle of the internal carotid artery	Notch of transducer oriented to right of patient Slowly advance probe, keep vessel in center of screen, show double lines on near and far walls	Overview of vessel orientation, wall thickness, plaques, and surrounding structures
2	Internal and external carotid artery Doppler recordings (one frame of each)	Pulsed wave Doppler of proximal 1 cm of each branch	Sample volume parallel to flow by beam steering and angle correction of ≤60 degrees If narrowing is seen, obtain pre- and post-velocities to document severity	Verifies anatomic orientation and may identify significant stenosis if present
3	Longitudinal plaque screen scan (3-5 beat cine-loop from at least 3 different angles in each segment)	Near and far walls of CCA, bulb, and internal carotid artery segments	Rotate 90 degrees from transverse plane with notch of transducer oriented toward head of patient Circumferential plaque screen scan from anterior, lateral, and posterior imaging planes	Identification and description of plaques

4 Select best images of distal 1 cm of CCA far wall from each of 3 angles; review loops, then measure from R-wave gated still frames

Complementary angles better represent overall wall thickness

5 Measure images in triplicate by tracing far wall blood-intima and media-adventitia interfaces using leading edge–to–leading edge method (Figure 5)
-Measure 1-cm length
-Assure that measurements from each angle are within 0.05 mm of others
-Plaques should be traced as part of CIMT

Triplicate measurements insure consistency, averaging increases precision
If more variation is identified, critically review images; only trace images with clear boundaries that are over-gained and are imaged perpendicular to artery

2013 ESH/ESC Guidelines for the management of arterial hypertension

EUROPEAN SOCIETY OF CARDIOLOGY®

3.7.2 Blood vessels

3.7.2.1 Carotid arteries

Ultrasound examination of the carotid arteries with measurement of intima media thickness (IMT) and/or the presence of plaques has been shown to predict the occurrence of both stroke and myocardial infarction, independently of traditional CV risk factors.[51,183–186] This holds true, both for the IMT value at the carotid bifurcations (reflecting primarily atherosclerosis) and for the IMT value at the level of the common carotid artery (reflecting primarily vascular hypertrophy). The relationship between carotid IMT and CV events is a continuous one and determining a threshold for high CV risk is rather arbitrary. Although a carotid IMT >0.9 mm has been taken as a conservative estimate of existing abnormalities in the 2007 Guidelines,[2] the threshold value for high CV risk was higher in the elderly patients of the Cardiovascular Health Study and in the middle-aged patients of the European Lacidipine Study on Atherosclerosis (ELSA) study (1.06 and 1.16 mm, respectively).[184,186] Presence of a plaque can be identified by an IMT ≥1.5 mm or by a focal increase in thickness of 0.5 mm or 50% of the surrounding carotid IMT value.[187] Although plaque has a strong independent predictive value for CV events,[51,183–185,188] presence of a plaque and increased carotid IMT added little to each other for predicting CV events and re-classifying patients into another risk category in the Atherosclerosis Risk In Communities (ARIC) study.[185] A recent systematic review concluded that the added predictive value of additional carotid screening may be primarily found in asymptomatic individuals at intermediate CV risk.[189]

Carotid intima-media thickness progression to predict cardiovascular events in the general population (the PROG-IMT collaborative project): a meta-analysis of individual participant data

Lancet 2012; 379: 2053–62

Matthias W Lorenz, Joseph F Polak, Maryam Kavousi, Ellisiv B Mathiesen, Henry Völzke, Tomi-Pekka Tuomainen, Dirk Sander, Matthieu Plichart, Alberico L Catapano, Christine M Robertson, Stefan Kiechl, Tatjana Rundek, Moïse Desvarieux, Lars Lind, Caroline Schmid, Pronabesh DasMahapatra, Lu Gao, Kathrin Ziegelbauer, Michiel L Bots, Simon G Thompson, on behalf of the PROG-IMT Study Group

Summary

Background Carotid intima-media thickness (cIMT) is related to the risk of cardiovascular events in the general population. An association between changes in cIMT and cardiovascular risk is frequently assumed but has rarely been reported. Our aim was to test this association.

Methods We identified general population studies that assessed cIMT at least twice and followed up participants for myocardial infarction, stroke, or death. The study teams collaborated in an individual participant data meta-analysis. Excluding individuals with previous myocardial infarction or stroke, we assessed the association between cIMT progression and the risk of cardiovascular events (myocardial infarction, stroke, vascular death, or a combination of these) for each study with Cox regression. The log hazard ratios (HRs) per SD difference were pooled by random effects meta-analysis.

Findings Of 22 eligible studies, 16 with 36 984 participants were included. During a mean follow-up of 7·0 years, 1519 myocardial infarctions, 1339 strokes, and 2028 combined endpoints (myocardial infarction, stroke, vascular death) occurred. Yearly cIMT progression was derived from two ultrasound visits 2–7 years (median 4 years) apart. For mean common carotid artery intima-media thickness progression, the overall HR of the combined endpoint was 0·97 (95% CI 0·94–1·00) when adjusted for age, sex, and mean common carotid artery intima-media thickness, and 0·98 (0·95–1·01) when also adjusted for vascular risk factors. Although we detected no associations with cIMT progression in sensitivity analyses, the mean cIMT of the two ultrasound scans was positively and robustly associated with cardiovascular risk (HR for the combined endpoint 1·16, 95% CI 1·10–1·22, adjusted for age, sex, mean common carotid artery intima-media thickness progression, and vascular risk factors). In three studies including 3439 participants who had four ultrasound scans, cIMT progression did not correlate between occassions (reproducibility correlations between r=–0·06 and r=–0·02).

Interpretation The association between cIMT progression assessed from two ultrasound scans and cardiovascular risk in the general population remains unproven. No conclusion can be derived for the use of cIMT progression as a surrogate in clinical trials.

Carotid arterial stiffness

- Arterial stiffness is one of the main determinants of SBP, PP and then CV events.

- Arterial stiffness has also an independent predictive value for CV events in patients with hypertension, diabetes, end-stage renal disease in elderly subjects and in general population.

- Arterial stiffening and cardiac function should be considered as an unicum: *ventricular arterial coupling*

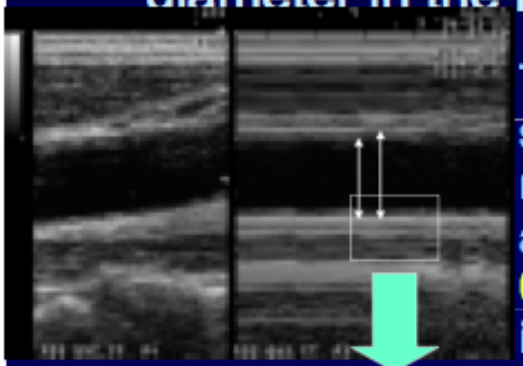
…and aortic disease

2014 ESC Guidelines on the diagnosis and treatment of aortic diseases

European Heart Journal Advance Access published August 29, 2014

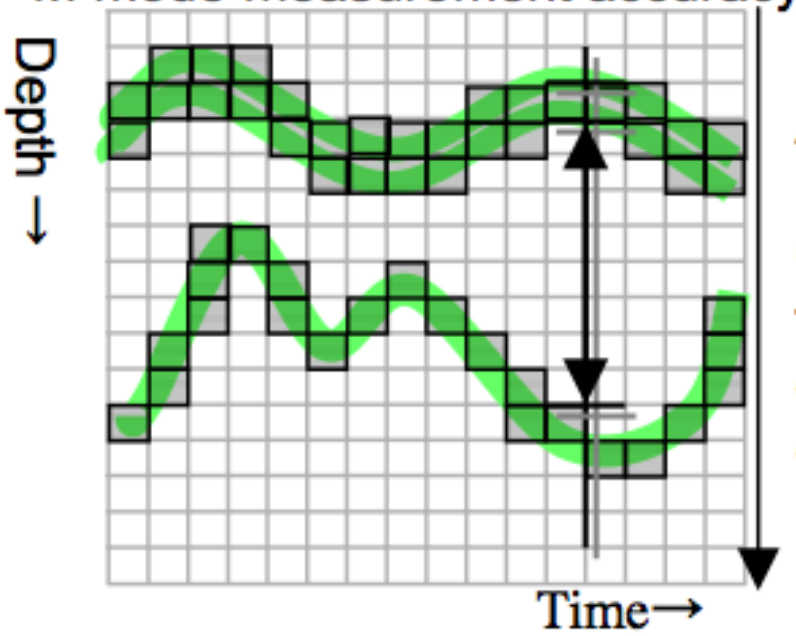
Measurement of blood vessel diameter in the M mode



The smallest step of measurement is approximately **0.1 mm** at best in the M mode.

In the ultrasound system, measurement is conducted by counting the number of pixels. Therefore, a resolution smaller than a pixel is not available.

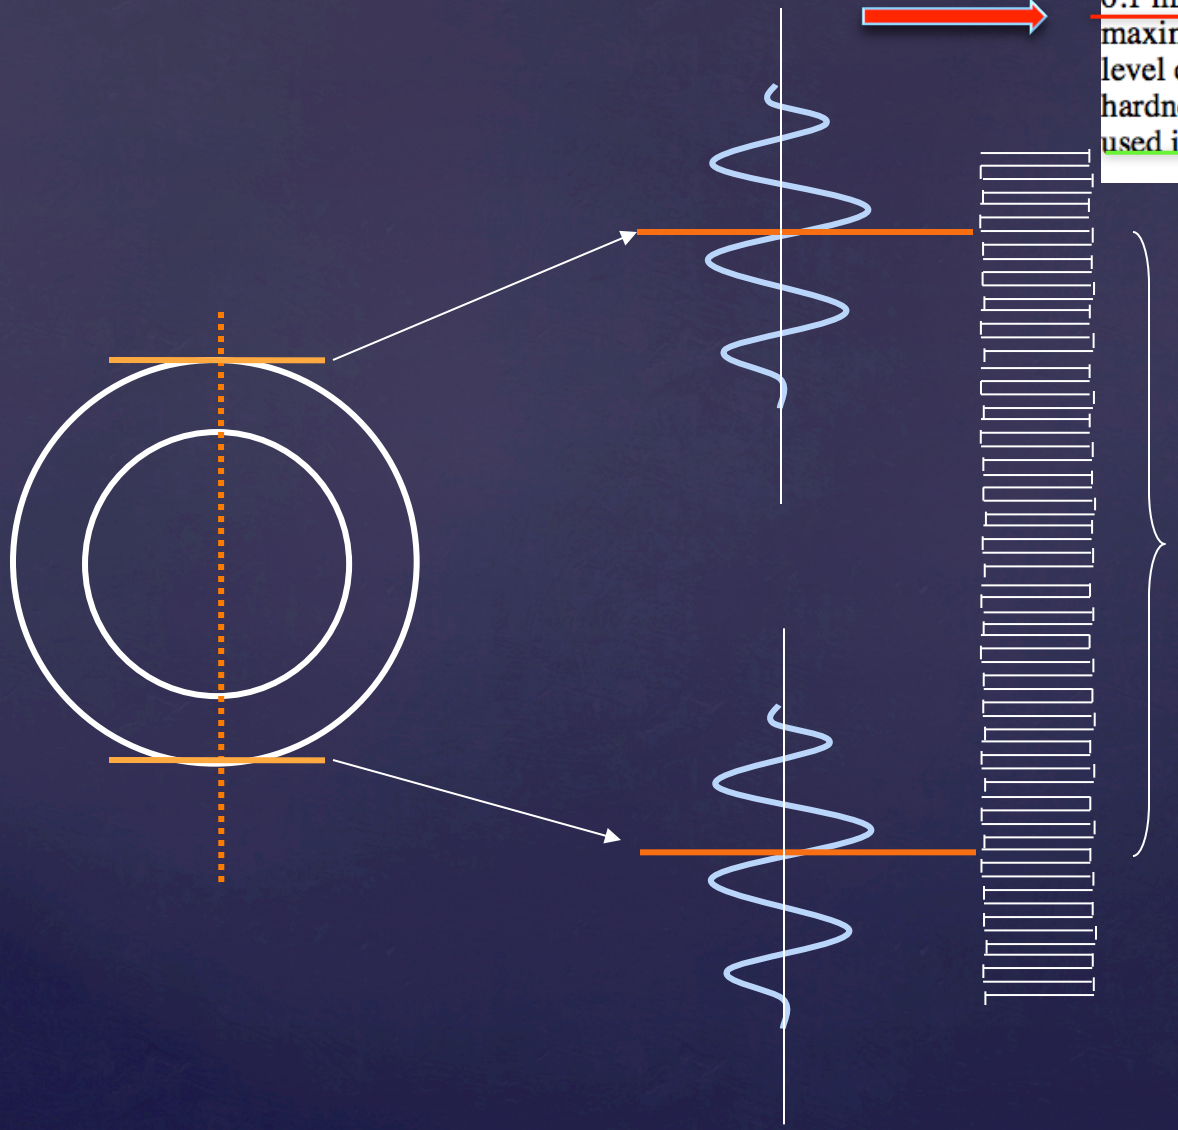
M mode measurement accuracy



Approx. 400 pixels.
0.1 mm/pixel for 4 cm diagnostic distance.

What's eTRACKING : Principle

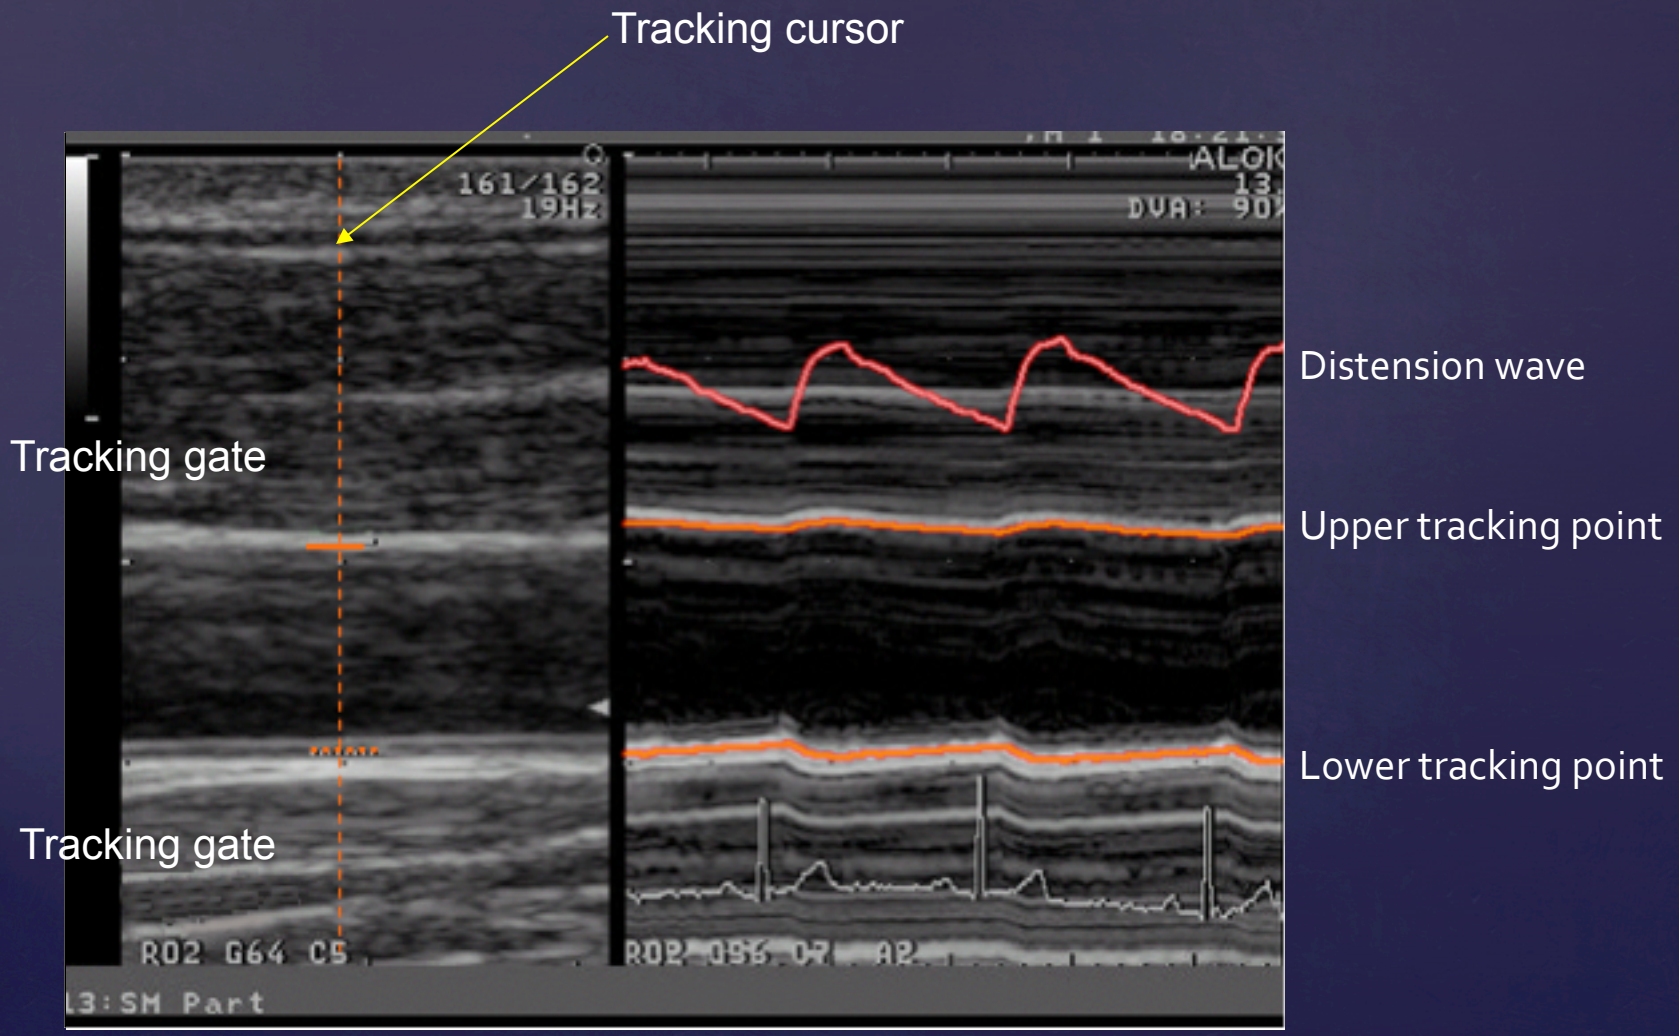
Even if the target area is enlarged, errors are inevitable by arbitrarily selecting the area of the membrane for measurement. Fineness of the M-mode measurement depends on distance resolution of the ultrasonic diagnostic unit and fineness (pixels) of the image. Generally, the smallest measuring step is approximately 0.1 mm. For hard arteries, the difference between maximum and minimum diameter is small, so that this level of accuracy is not enough to correctly evaluate the hardness. To solve the problem, RF echo tracking is used in eTRACKING.



The distance between two gates shows the vessel diameter.

At 10 MHz frequency precision is 0.01mm

Movement of the vessel wall is tracked automatically by simply setting the tracking gate on the B-mode image. Displays waveforms of changes in vessel diameter (distension wave) in real time.



Calculated parameters

Ps: systolic pressure
Pd: diastolic pressure
Ds: maximum vessel diameter
Dd: minimum vessel diameter

β (stiffness parameter): index of arterial stiffness

$\beta = \ln(Ps / Pd) / [(Ds - Dd) / Dd]$

Calculated from changes in vessel diameter and blood pressure
Arterial stiffness ↑ β value ↑
Less dependent on blood pressure

Ep (pressure-strain elasticity modulus): index of vessel elasticity

$Ep = (Ps - Pd) / [(Ds - Dd) / Dd]$

Calculated from changes in vessel diameter and blood pressure
Arterial elasticity ↓ Ep ↑
The value greatly varies with blood pressure even in the same blood vessel.

AC (arterial compliance): index of blood vessel compliance

$AC = \pi(Ds \times Ds - Dd \times Dd) / [4 (Ps - Pd)]$

Calculated from changes in blood vessel cross-sectional area and blood pressure
Arterial compliance ↑ AC ↑

PWVβ　One –Point Pulse wave velocity

PWV is mainly related to the elastic properties of the arterial wall.

PWV is well known as a parameter to assess the atherosclerosis.

Conventional PWV has been based on the two point measurement.

PWV is the velocity at which the pulse wave travel between known distance.

When the artery becomes stiffer, the PWV shows higher value.

This time, we developed one point pulse wave velocity method derived from Stiffness parameter β

Definitional equation $C = \sqrt{(\beta P / 2\rho)}$

P：Diastolic blood pressure

ρ：blood density (1050 Kg/m^3)

Arterial stiffness:regional and local stiffness

EHJ 2006;27:2588

Although carotid-femoral PWV and carotid stiffness provide similar information on the impact of ageing on large artery stiffness in normal subjects, this is not the case for high blood pressure and/or diabetes. In these cases, the aorta stiffened more than the carotid artery with age and other CV risk factors.[66] Thus, aortic stiffness and carotid stiffness cannot be used as interchangeable predictors in high-risk patients.

Carotid and Aortic Stiffness

Determinants of Discrepancies

Anna Paini, Pierre Boutouyrie, David Calvet, Anne-Isabelle Tropeano, Brigitte Laloux, Stéphane Laurent

Abstract—Several studies have shown that aortic stiffness was an independent predictor for cardiovascular events. However, data are less consistent concerning carotid stiffness. We analyzed the determinants of the discrepancies between aortic and carotid stiffness in different populations with contrasting cardiovascular risk factors: 94 healthy normotensives (NT), 243 nondiabetic hypertensives (HT), and 126 patients with hypertension and type 2 diabetes (T2D). Aortic stiffness was measured with carotid-femoral pulse wave velocity. Common carotid stiffness was determined from the relative stroke change in diameter (measured with a high-resolution echotracking system) and carotid pulse pressure (measured with applanation tonometry) and was expressed in the same dimensions as pulse wave velocity (m/s). We identified the various factors explaining the discrepancies between aortic and carotid stiffness by multivariate analysis of the residuals of the correlation between aortic and carotid stiffness. The strength of the correlation between aortic and carotid stiffness became weaker as the number of cardiovascular risk factors increased (NT, r^2=0.41; HT, r^2=0.16; and T2D, r^2=0.11), whereas we observed the opposite for the discrepancies (residuals) between aortic and carotid stiffness, of which an increasing part was explained (11% in NT, 22% in HT, and 45% in T2D) primarily by aging. In conclusion, although carotid-femoral pulse wave velocity and carotid stiffness provided similar information on the impact of aging on large artery stiffness in normal subjects, this was not the case for high blood pressure and/or diabetes. In these cases, the aorta stiffened more than the carotid artery with age and other cardiovascular risk factors. (***Hypertension***. 2006;47:371-376.)

Values are hazard ratio (95% confidence interval). Hazard ratios are indicated per 1 SD lower distensibility (DC) and compliance coefficient (CC) and per 1 SD higher Young's elastic modulus (YEM). Model 1: adjusted for age, sex, and glucose metabolism status. Model 2: model 1 plus mean arterial pressure. Model 3: model 2 plus prior cardiovascular disease, body mass index, triglycerides, total/HDL cholesterol ratio, estimated glomerular filtration rate, microalbuminuria, physical activity, and smoking habits. The number of participants and events available for analysis with incident CV events/all-cause mortality for carotid DC, CC, and YEM: 533 (130 events)/579 (96 events); for femoral DC and CC: 461 (111 events)/498 (77 events); and for brachial DC and CC: 478 (116 events)/517 (81 events).

Abbreviations as in Table 1.

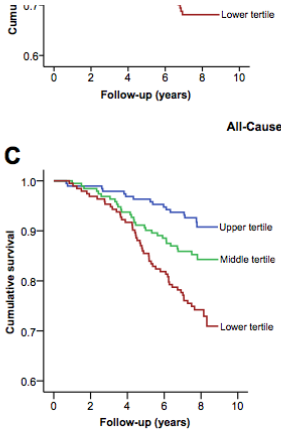

Figure 2 Kaplan-Meier Curves for Incident CV Events and All-Ca

Kaplan-Meier curves for incident cardiovascular (CV) events and all-cause mortality femoral arteries (**B and D**).

Table 3 Associations of the cfPWV, Aix, and SAC With Incident Cardiovascular Events and All-Cause Mortality

Model	cfPWV	Aix	SAC	
			Time-Decay Method	SV/Aortic PP
Incident Cardiovascular Events				
1	1.57 (1.29–1.92)	1.08 (0.89–1.31)	1.09 (0.88–1.35)	1.15 (0.90–1.47)
2	1.56 (1.27–1.93)	1.05 (0.86–1.28)	1.03 (0.81–1.30)	1.09 (0.84–1.43)
3	1.56 (1.23–1.98)	0.99 (0.81–1.22)	1.00 (0.79–1.26)	1.13 (0.87–1.47)
All-Cause Mortality				
1	1.27 (0.99–1.63)	1.05 (0.84–1.32)	1.22 (0.92–1.61)	1.05 (0.70–1.58)
2	1.18 (0.88–1.57)	1.19 (0.92–1.54)	1.06 (0.78–1.43)	1.05 (0.67–1.65)
3	1.13 (0.83–1.54)	0.93 (0.73–1.18)	1.04 (0.76–1.41)	1.01 (0.73–1.41)

Values are hazard ratio (95% confidence interval). Hazard ratios are indicated per 1 SD higher carotid femoral pulse wave velocity (cfPWV) and aortic augmentation index (Aix) and per 1 SD lower systemic arterial compliance (SAC). Model 1: adjusted for age, sex, and glucose metabolism status. Model 2: model 1 plus mean arterial pressure and heart rate. Model 3: model 2 plus prior cardiovascular disease, body mass index, triglycerides, total/HDL cholesterol ratio, estimated glomerular filtration rate, microalbuminuria, physical activity, and smoking habits. Number of participants and events available for analysis with incident cardiovascular events/all-cause mortality for cfPWV: 215 (53 events)/237 (36 events); for Aix: 500 (120 events)/543 (87 events); for SAC (time-decay method): 457 (110 events)/492 (77 events); and for SAC (SV/aortic PP) 448 (106 events)/482 (70 events).

PP = pulse pressure; SV = stroke volume; other abbreviations as in Table 1.

Carotid Artery Stiffness and Diastolic Function in Subjects without Known Cardiovascular Disease

Olga Vriz, MD, Eduardo Bossone, MD, PhD, FESC, FACC, Manola Bettio, MD, Daniela Pavan, MD, Scipione Carerj, MD, and Francesco Antonini-Canterin, MD, *Udine, Milan, Pordenone, and Messina, Italy*

JASE 2011

Background: The aim of this study was to investigate the relationship between carotid artery stiffness and diastolic function in a cohort of subjects without known cardiovascular risk factors and/or overt cardiovascular disease.

Methods: Ninety-two healthy subjects underwent transthoracic echocardiographic Doppler and carotid echo-tracking studies. Measurements of local arterial stiffness were obtained at left common carotid artery level; stiffness parameter (β), and pressure-strain elasticity modulus (Ep) were calculated as well as intima-media thickness (IMT).

Results: Stiffness parameter and Ep were correlated inversely with transmitral E wave ($P < .01$), E/A ratio, and septal Em ($P < .01$) and positively with A wave ($P < .001$). IMT was also associated with A wave, E/A ratio, Em, and Am but not with E wave. No association was found between IMT, β, and Ep. The correlation between arterial stiffness and left ventricular diastolic function remained significant after multivariate adjustment for age, sex, pulse pressure, and body mass index, but not with IMT.

Conclusions: In healthy subjects, changes in central carotid stiffness are in line with left ventricular diastolic function independently of age, sex, pulse pressure, and body mass index. (J Am Soc Echocardiogr

Interplay between arterial stiffness and diastolic function: a marker of ventricular-vascular coupling

Concetta Zito[a], Moemen Mohammed[a], Maria Chiara Todaro[a], Bijoy K. Khandheria[b], Maurizio Cusmà-Piccione[a], Giuseppe Oreto[a], Pietro Pugliatti[a], Mohamed Abusalima[c], Francesco Antonini-Canterin[d], Olga Vriz[e] and Scipione Carerj[a]

Aims We evaluated the interplay between left ventricular diastolic function and large-artery stiffness in asymptomatic patients at increased risk of heart failure and no structural heart disease (Stage A).

Methods We divided 127 consecutive patients (mean age 49 ± 17 years) with risk factors for heart failure who were referred to our laboratory to rule out structural heart disease into two groups according to presence (Group 1, $n = 35$) or absence (Group 2, $n = 92$) of grade I left ventricular diastolic dysfunction. Doppler imaging with high-resolution echo-tracking software was used to measure intima-media thickness (IMT) and stiffness of carotid arteries.

Results Group 1 had significantly higher mean age, blood pressure, left ventricular mass index, carotid IMT and arterial stiffness than Group 2 ($P<0.05$). Overall, carotid stiffness indices (β-stiffness index, augmentation index and elastic modulus) and 'one-point' pulse wave velocity each showed inverse correlation with E-wave velocity, E′ velocity and E/A ratio, and direct correlation with A-wave velocity, E-wave deceleration time and E/E′ ratio ($P<0.05$). Arterial compliance showed negative correlations with the echocardiographic indices of left ventricular diastolic function ($P<0.05$). On logistic regression analysis, age, hypertension, SBP, pulse pressure, left ventricular mass index, carotid IMT and stiffness parameters were associated with grade I left ventricular diastolic dysfunction ($P<0.05$ for each). However, on multivariate logistic analysis, only 'one-point' pulse wave velocity and age were independent predictors ($P = 0.038$ and $P = 0.016$, respectively).

Conclusion An independent association between grade I left ventricular diastolic dysfunction and increased arterial stiffness is demonstrated at the earliest stage of heart failure. Hence, assessment of vascular function, beyond cardiac function, should be included in a comprehensive clinical evaluation of these patients.

J Cardiovasc Med 2014, 15:000–000

Italian Federation of Cardiology

Conclusion 1

- ✓ The presence of subclinical arterosclerosis (increse C-IMT, increse carotid stiffness) is a disease itselfe over an additional predictive value.
- ✓ C-IMT and arterial stiffness have incremental value on risk assessment over FRS especially among intermediate risk cohort
- ✓ C-IMT measurements need to be better standarized to be constant and rialable in every-day clinical practice

Conclusion 2
Clinical application of arterial stiffness in cardiac disease assessment

Carotid Intima-Media Thickness and Antihypertensive Treatment

A Meta-Analysis of Randomized Controlled Trials

Ji-Guang Wang, MD, PhD; Jan A. Staessen, MD, PhD; Yan Li, MD, PhD;
Luc M. Van Bortel, MD, PhD; Tim Nawrot, PhD; Robert Fagard, MD, PhD;
Franz H. Messerli, MD; Michel Safar, MD

Background and Purpose—Hypertension promotes carotid intima-media thickening. We reviewed the randomized controlled trials that evaluated the effects of an antihypertensive drug versus placebo or another antihypertensive agent of a different class on carotid intima-media thickness.

Methods—We searched the PubMed and the Web of Science databases for randomized clinical trials, published in English before 2005, and included 22 trials.

Results—In 8 trials including 3329 patients with diabetes or coronary heart disease, antihypertensive treatment initiated with an angiotensin-converting enzyme (ACE) inhibitor, a β-blocker, or a calcium-channel blocker (CCB), compared with placebo or no-treatment, reduced the rate of intima-media thickening by 7 μm/year (P=0.01). In 9 trials including 4564 hypertensive patients, CCBs, ACE inhibitors, an angiotensin II receptor blocker or an α-blocker, compared with diuretics or β-blockers, in the presence of similar blood pressure reductions, decreased intima-media thickening by 3 μm/year (P=0.03). The overall beneficial effect of the newer over older drugs was largely attributable to the decrease of intima-media thickening by 5 μm/year (P=0.007) in 4 trials of CCBs involving 3619 patients. In 5 trials including 287 patients with hypertension or diabetes, CCBs compared with ACE inhibitors did not differentially affect blood pressure, but attenuated intima-media thickening by 23 μm/year (P=0.02). The treatment induced changes in carotid intima-media thickness correlated with the changes in lumen diameter (P=0.02), but not with the differences in achieved blood pressure (P>0.53).

Conclusions—CCBs reduce carotid intima-media thickening. This mechanism might contribute to their superior protection against stroke. (***Stroke*. 2006;37:1933-1940.)**
