Validation of Magnetic Resonance Myocardial Perfusion Imaging With Fractional Flow Reserve for the Detection of Significant Coronary Heart Disease

Background—Magnetic resonance myocardial perfusion imaging (MRMPI) has a number of advantages over the other noninvasive tests used to detect reversible myocardial ischemia. The majority of previous studies have generally used quantitative coronary angiography as the gold standard to assess the accuracy of MRMPI; however, only an approximate relationship exists between stenosis severity and functional significance. Pressure wire-derived fractional flow reserve (FFR) values <0.75 correlate closely with objective evidence of reversible ischemia. Accordingly, we have compared MRMPI with FFR.

Methods and Results—One hundred three patients referred for investigation of suspected angina underwent MRMPI with a 1.5-T scanner. The stress agent was intravenous adenosine ($140 \mu\text{g} \cdot \text{kg}^{-1} \cdot \text{min}^{-1}$), and the first-pass bolus contained 0.1 mmol/kg gadolinium. In the following week, coronary angiography with pressure wire studies was performed. FFR was recorded in all patent major epicardial coronary arteries, with a value <0.75 denoting significant stenosis. MRMPI scans, analyzed by 2 blinded observers, identified perfusion defects in 121 of 300 coronary artery segments (40%), of which 110 had an FFR <0.75 . We also found that 168 of 179 normally perfused segments had an FFR ≥ 0.75 . The sensitivity and specificity of MRMPI for the detection of functionally significant coronary heart disease were 91% and 94%, respectively, with positive and negative predictive values of 91% and 94%.

Conclusion—MRMPI can detect functionally significant coronary heart disease with excellent sensitivity, specificity, and positive and negative predictive values compared with FFR. (*Circulation*. 2009;120:2207-2213.)

Diagnostic Ability of MRMPI

	FFR <0.75	FFR ≤ 0.8	DS $\geq 70\%$
Sensitivity, %	90.9 (84.2–97.6)	81.9 (73.5–90.4)	97.3 (92.8–101.8)
Specificity, %	93.9 (88.9–98.8)	98.1 (95.0–101.2)	78.1 (70.5–85.6)
PPV, %	90.9 (84.3–97.5)	97.5 (94.0–101.0)	59.0 (47.5–70.6)
NPV, %	93.9 (88.9–98.9)	85.5 (78.2–92.8)	98.9 (96.9–100.9)

MRMPI Compared With FFR at 2 Cutoff Values (0.75 and 0.8) and Degree of Stenosis by QCA

	FFR <0.75	FFR ≥ 0.75	Total	FFR ≤ 0.8	FFR >0.8	Total	DS $\geq 70\%$	DS $<70\%$	Total
Positive MRMPI	110	11	121	118	3	121	72	50	122
Negative MPMRI	11	168	179	26	153	179	2	178	180
Total	121	179	300	144	156	300	74	228	302

Results are expressed per coronary artery territory.

Conclusions

CMR allows evaluation of AMI and complications

Patients with suspected ACS but with no angiographic evidence of CAD should undergo CMR for alternative diagnosis (Myocarditis, Tako-tsubo etc)

Stress CMR is an alternative of stress echo in low-risk patients

Main disadvantages of MRI are contraindications and the poor diffusion of the technique
